For example, signaling protocols can support QoS mapping. In general, the QoS of a PDU would be mapped to the QoS of the PDU as it is received. However, if a "thin" PDU or one with only a very small number of payload bits are received, it can be difficult to determine an adequate QoS for the PDU. This is because, for such a PDU, only a very small amount of information, e.g., the receiver address, can be mapped to the QoS of the PDU. To further illustrate, a receiver uses header information, such as an IPv4/IPv6 receiver address and an encoding protocol of the packet to determine the QoS of a received PDU. In accordance with certain embodiments, one way to determine the QoS of a PDU, which may include a header, is to apply the header to an error correcting code, such as a Reed-Solomon code. For a PDU that is received, with the header but without any payload bits, error correcting codes can be applied to the header to determine the QoS of the PDU, based on, e.g., the number of header bits corrected by the error correcting code. For a PDU that is received, with the header and a payload of a sufficient number of payload bits, the number of payload bits can be used to map the PDU to a QoS. For example, a PDU including a header and a payload of more than 64 bytes can be assumed to be less reliable than a PDU including a header and a payload of 64 bytes or less. For such PDUs, a number of payload bits is used to determine the QoS. Simultaneous occurrence of gastric and small intestinal neuroendocrine tumors in a patient with pheochromocytoma
