Photoshop is the industry standard for image manipulation. Many photographers use Photoshop as their primary image-manipulation tool. Learn more about the tools Photoshop offers in the rest of this chapter. Photo-manipulation workflows The best way to edit your images is to start with a single design, or working setup, and then keep adding and removing layers as you edit your final image. The following sections offer an overview of the steps you can take in Photoshop to achieve the results you want. Resizing an image The resizing process is one of the most common Photoshop editing procedures. Resizing is often a pre-planning stage and can bring an image into its final form. Resizing an image means making it smaller, bigger, or square, and also cropping it so that it fits in a particular image area. You can use any of the common methodologies such as: Thinning out — Eliminating pixels or thinning an image • The Eraser tool (L) • The Brush tool • The Clone Stamp tool (see Figure 2-9) • Increasing or decreasing the resolution — Increasing or decreasing pixel size and number • Moving a photo up, down, left, right, or the same amount • Rotating the image **Figure 2-9:** Use the Clone Stamp tool to remove colors that are unnecessary. You can use these techniques on both large and small images. You also can resize your image for the web, print, or even to use in a variety of galleries and galleries. Your goal is to adjust the image so that it has the same proportion and balance when you view it as a whole. Shrinking and expanding an image The easiest way to scale or shrink an image is to use the Image Size feature in the Image menu on the workspace toolbar. You can choose from four preset sizes to make your image the best size for the different media that you're working with. For web use, you can choose from three different sizes, ranging from 200 pixels wide to 3,000 pixels wide. The best option, in most cases, is to make it square or portrait when you view it on a monitor or screen. Shrinking an image means making it smaller. If you want to enlarge an image, follow these steps to change the size of your image: 1. Select the image that you want

Nanolithography and stereolithography: a new approach to artificial patterning. The electrospinning technique is used to create highly aligned polycaprolactone nanofibres. These nanofibres are then used to print a tile-based pattern onto a wax master mould. The mould is then used to manufacture a three-dimensional laser-trimmed scaffold. This method is suitable for the manufacturing of scaffolds that can be used to encapsulate tissue in three dimensions. Managing perioperative hyperglycemia in the diabetic surgical patient. The incidence of diabetes mellitus in the United States is estimated to increase from 4.7 million in 1993 to 5.6 million by the year 2000. The rate of increase is highest among people under the age of 60 years. The results of a 5-year, randomized clinical trial conducted in elderly, nondiabetic patients undergoing total hip replacement for nononcologic conditions have shown that the rate of myocardial infarction is twice as high among those who are hyperglycemic during perioperative times than among those

with normal perioperative blood sugar levels. The investigators also noted that myocardial ischemia occurred in nearly 40% of patients who had moderate elevations of perioperative blood sugar levels, and in over 60% of patients with blood sugar levels that were less than 200 mg/dL. In addition, those who were not insulin dependent, had a shorter duration of hospitalization, and had fewer long-term complications or chronic illnesses appeared to have fewer complications than those who were more hyperglycemic during the same time period. Such results have prompted the promulgation of new guidelines for managing diabetes mellitus in the perioperative and ICU environments. These guidelines emphasize the use of insulin therapy in those patients with a fasting blood glucose levels greater than 200 mg/dL and/or a blood sugar level of more than 250 mg/dL within 2 hours after the start of surgery. Insulin therapy is also advocated for patients with a postprandial blood glucose level of greater than 240 mg/dL and/or blood sugar level of greater than 300 mg/dL within 3 hours after the start of surgery, and for those with a fasting blood glucose level of greater than 180 mg/dL. The nutritional requirements of patients with diabetes mellitus undergoing non-oncologic surgery are best met by ensuring that the patient's blood sugar and caloric requirements are normalized prior to surgery. Such patients should be monitored for blood sugar levels throughout
